Attorney, Agent, or Firm—Baker & Botts, L.L.P.*[57] **ABSTRACT**

A communication system (10) includes a number of subscribers (12) coupled to a central office (14) using twisted pair subscriber lines (16). The central office (14) includes a telephone switch (56) that provides telephone service to the subscribers (12), and a communication server (58) having a plurality of XDSL modems (160) that provide data service to the subscribers (12). The communication server (58) allows over-subscription of data service to subscribers (12).

FIG. 7

FIG. 8

COMMUNICATION SERVER APPARATUS AND METHOD

TECHNICAL FIELD OF THE INVENTION

This invention relates in general to data communication, and more particularly to a communication server apparatus and method.

BACKGROUND OF THE INVENTION

A communication server provides access to communication facilities. For example, a communication server having a bank of modems may provide subscriber access to the modems for data communication. A communication server may be associated with its own dedicated communication network, or with an existing communication network, such as the public switched telephone network (PSTN).

As communication networks provide greater connectivity and access to information, there is an increasing demand for data communication at higher rates. One solution to provide increased data rates replaces existing twisted pair wiring with high bandwidth media, such as coaxial cables or fiber optic links. Other solutions adopt improved communication techniques using the existing hardware infrastructure. For example, digital subscriber line (XDSL) technology provides higher bandwidth data service over existing twisted pair wiring.

To deliver data service to the subscriber, a communication server may provide a dedicated or permanent connection to its communication facilities. For example, an existing communication server at a central office provides enough communication facilities to simultaneously service all PSTN subscribers. However, all telephone subscribers may not desire data service. Furthermore, the subscribers that desire data service may not simultaneously access the communication server.

SUMMARY OF THE INVENTION

In accordance with the present invention, the disadvantages and problems associated with communication servers have been substantially reduced or eliminated. In particular, a communication server is disclosed that provides data service to a number of subscribers using a reduced number of XDSL communication facilities.

In accordance with one embodiment of the present invention, a communication system includes a number of computers, each computer having a first XDSL modem that communicates information. Twisted pair subscriber lines are coupled to the computers, which are in turn coupled to a splitter. The splitter splits each twisted pair subscriber line into a twisted pair data line and a twisted pair phone line. A communication server provides data service using the twisted pair data lines and includes a number of second XDSL modems that communicate information with the first XDSL modems. The number of second XDSL modems is less than the number of twisted pair data lines.

In accordance with another embodiment of the present invention, a communication server located at a central office couples to a number of twisted pair data lines, each twisted pair data line is coupled to an associated twisted pair subscriber line by a splitter. The communication server includes a number of XDSL modems and a switch coupled to the XDSL modems. The switch couples the twisted pair data lines to the XDSL modems, wherein the number of XDSL modems is less than the number of twisted pair data lines. Polling circuitry polls in succession the twisted pair

data lines, and a detector detects a need for data service on a selected twisted pair data line. A processor selects one of the XDSL modems in response to detecting the need and directs the switch to couple the selected twisted pair data line to the selected XDSL modem.

Important technical advantages of the present invention include a communication server that provides data service to a number of subscribers using a reduced number of XDSL communication facilities. Over-subscription of data service is accomplished by selectively coupling a number of twisted pair data lines to a reduced number of XDSL modems. A controller polls the data lines in succession to determine which subscribers of the communication system need data service. Upon detecting a need for data service on a selected data line, the controller directs a switch to couple the selected data line to an available modem. The communication server may then provide data service suitable for high bandwidth applications, such as video-on-demand, multimedia, or Internet access.

Another important technical advantage of the present invention includes a communication server that provides over-subscribed XDSL data service using the existing infrastructure of the public switched telephone network (PSTN). Asymmetric digital subscriber line (ADSL), symmetric digital subscriber line (SDSL), high-speed digital subscriber line (HDSL), very high-speed digital subscriber line (VDSL), or other suitable XDSL technology can provide higher bandwidth data service over existing twisted pair wiring. These technologies may support data service simultaneously with traditional telephone service using a separation technique, such as frequency division multiplexing. In one embodiment, a splitter divides each incoming twisted pair subscriber line into a twisted pair phone line and a twisted pair data line. The phone line is coupled to a telephone switch to provide telephone service and the data line is coupled to the communication server to provide over-subscribed XDSL data service. The communication server and splitter may be located at a central office of the PSTN.

Another important technical advantage of the present invention includes the management and monitoring of XDSL data service provided to subscribers. To accomplish this, the communication server maintains an activity table to determine status information on twisted pair data lines and XDSL modems. In addition, the communication server can track subscriber usage, monitor subscriber information, and generate billing and demographic information. In a particular embodiment, an activity detector disconnects a subscriber after a predetermined period of inactivity to release a modem for use by another subscriber. Other important technical advantages are readily apparent to one skilled in the art from the following figures, descriptions, and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention, and for further features and advantages, reference is now made to the following description taken in conjunction with the accompanying drawings, in which:

FIG. 1 illustrates a communication system that provides telephone and data service;

FIG. 2 illustrates a communication server in the communication system;

FIG. 3 illustrates in more detail the controller of the communication server;

FIG. 4 illustrates in more detail the switch and modem pool of the communication server;

FIG. 5 illustrates in more detail the transceiver in the controller of the communication server;

FIG. 6 illustrates in more detail the detector in the controller of the communication server;

FIG. 7 illustrates an activity table used by the controller of the communication server;

FIG. 8 is a flow chart of a method for coupling a data line to a modem in the communication server; and

FIG. 9 is a flow chart of a method to decouple a data line from a modem in the communication server.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 illustrates a communication system 10 that provides both telephone and data service to a subscriber 12. A central office 14 is coupled to subscriber 12 using subscriber line 16. In operation, central office 14 provides telephone and data service to subscriber 12 using subscriber line 16. Subscriber line 16 supports simultaneous telephone and data service using twisted pair wiring.

Subscriber 12 includes a telephone 20 and a computer 22, both coupled to an interface 24. A splitter 25 is coupled to subscriber line 16 and operates to split subscriber line 16 into a twisted pair phone line 26 and a twisted pair data line 28. Phone line 26 is coupled to telephone 20 using interface 24. Similarly, data line 28 is coupled to computer 22 using interface 24. Subscriber 12 refers to one or more components at the subscriber premises shown in FIG. 1, as well as the user of these components.

Telephone 20 is a traditional telephone transceiver, a cordless telephone transceiver, or any other device suitable for allowing voice communication over telephone line 26. Computer 22 comprises a mainframe device, miniframe device, server, desktop personal computer, notebook personal computer, or other suitable computing device having an XDSL modem 30 that communicates data using data line 28. Modem 30 couples to other components of computer 22 using a Peripheral Component Interconnect (PCI) bus, an Industrial Standard Architecture (ISA) bus, a Personal Computer Memory Card International Association (PCMCIA) interface, or any other suitable technology that provides input/output capability to computer 22. The selection and design of modem 30 for computer 22 may depend on the type or functionality of computer 22, as well as the data service rate supported by data line 28.

Modem 30 transmits and receives data in communication system 10 using any suitable digital subscriber line technology, referred to generally as XDSL. Modem 30 also supports Ethernet, Fast Ethernet, V.35 data protocol, frame relay, asynchronous transfer mode (ATM), switched multi-megabit data service (SMDS), high-level data link control (HDLC), serial line Internet protocol (SLIP), point-to-point protocol (PPP), transmission control protocol/Internet protocol (TCP/IP), or any other appropriate protocol, collectively referred to as digital protocol. For example, computer 22 may include a network interface 31 to receive data from central office 14 or to further communicate data to a local area network (LAN), wide area network (WAN), or other suitable network coupled to computer 22 using link 18. In general, modem 30 translates information between the communication protocol supported by communication system 10 and the digital protocol supported by computer 22.

Communication system 10 includes numerous other twisted pair subscriber lines 16 coupled to other subscribers 12. In an exemplary embodiment, central office 14 provides phone and data service to one thousand subscribers, with each subscriber 12 including one or more components described above at its premises. The subscribers and sub-

scriber lines in communication system 10 are referred to collectively in the plural as subscribers 12 and subscriber lines 16.

Interface 24 couples phone line 26 to telephone 20, and data line 28 to computer 22. In one embodiment, interface 24 provides additional couplings to additional telephones 20 and computers 22 at subscriber 12. Splitter 25 is a passive or active splitter that divides subscriber line 16 into phone line 26 and data line 28 of the same type. Throughout this description, phone line 26 and data line 28 may be referred to specifically, or collectively as part of subscriber line 16.

Subscriber line 16 couples subscriber 12 to central office 14. Subscriber line 16 comprises twisted pair wiring that is commonly installed at subscriber premises and as the local loop in many public switched telephone networks (PSTNs). Subscriber line 16 may be unshielded twisted pair (UTP), shielded twisted pair (STP), or other suitable type or category of twisted pair wiring made of copper or other suitable material. Phone line 26 and data line 28 associated with subscriber line 16 may be the same or different type or category of twisted pair wiring.

Central office 14 includes a splitter 50 coupled to subscriber line 16. Like splitter 25 at subscriber 12, splitter 50 at central office 14 is a passive or active splitter that divides subscriber line 16 into a twisted pair phone line 52 and a twisted pair data line 54. Phone line 52 and data line 54 associated with subscriber line 16 may be the same or different type or category of twisted pair wiring. A telephone switch 56 at central office 14 is coupled to phone line 52 to provide plain old telephone system (POTS) service to subscriber 12. Telephone switch 56 also represents other components in the PSTN or other suitable voice communication network, such as switches, wireline or wireless links, satellites, microwave uplinks, and other communication facilities to deliver telephone service to subscriber 12.

A communication server 58 is coupled to splitter 50 using data line 54. As described in detail below, communication server 58 manages the provisioning of data service to subscriber 12. Communication server 58 performs off-hook detection to determine if subscriber 12 desires data service. Specifically, communication server 58 couples a modem to subscriber line 16 upon detecting a need for data service from computer 22. Communication server 58 tracks subscriber usage, monitors subscriber information, and generates billing and demographic information, as described below.

The data off-hook detector in communication server 58 can use one of several methods to determine whether subscriber 12 should be connected to an XDSL modem. The off-hook detector may monitor direct current voltages, electrical tones, data link frames, or any other protocol or data sequencing to determine whether subscriber 12 needs data access. The off-hook detector in communication server 58 may monitor electrical tones generated by modem 30 while in the process of training, notching, equalizing, or performing any other task that puts electrical tones onto subscriber line 16 and its associated data line 54. Communication server 58 may also detect frames or packets. These frames or packets could be Ethernet, ATM, HDLC, or any suitable data communications frame format. The off-hook detector in communication server 58 could also examine various protocols such as TCP/IP, PPP, or any other suitable network protocol or data stream.

Communication server 58 multiplexes modem digital outputs into a multiplexed digital line 62 for delivery to a router or other network device 60. In one embodiment,

multiplexed digital line 62 carries a single bidirectional and multiplexed signal for all subscribers 12 in communication system 10. Signals on multiplexed digital line 62 may support any appropriate digital protocol used by network device 60. A communication network 64, such as a global communication network like the Internet, is coupled to network device 60. Communication network 64 may also include a synchronous optical network (SONET), a frame relay network, an asynchronous transfer mode (ATM) network, a T1, T3, E1, or E3 network, or any other suitable communication network.

One important technical advantage of the present invention is the ability to over-subscribe the XDSL communication facilities of communication server 58 to service an increasing number of subscribers 12 in communication system 10. Communication server 58 may couple to the same number and type of data lines 54 as represented by subscriber lines 16 in communication system 10. For example, if central office 14 services one thousand subscribers 12 using twisted pair subscriber lines 16, then data lines 54 coupled to communication server 58 may represent as many as one thousand twisted pair lines.

In one embodiment, not all subscribers 12 in communication system 10 desire access to data service provided by communication server 58. Splitter 50 need not provide a separate data line 54 for those subscribers 12 that only desire phone service from telephone switch 56. As more subscribers 12 desire access to data service, the XDSL communication capabilities of splitter 50 and communication server 58 may be supplemented in a modular and cost effective manner to meet the demand.

Communication system 10 supports data service over subscriber lines 16 using asymmetric digital subscriber line (ADSL), symmetric digital subscriber line (SDSL), high-speed digital subscriber line (HDSL), very high-speed digital subscriber line (VDSL), or any other suitable technology that allows high rate data service over twisted pair wiring. All of these technologies are referred to collectively as XDSL or communication protocol. In one embodiment, subscriber line 16 and components of subscriber 12 and central office 14 support communication using ADSL techniques that comply with ANSI standard T1.413. In another embodiment, ADSL communication over subscriber line 16 may be performed using the carrier-less amplitude phase modulation (CAP) technique developed by AT&T Corporation.

In an ADSL communication system, the downlink data rate 32 from central office 14 to subscriber 12 is greater than the uplink data rate 34 from subscriber 12 to central office 14. This allows high bandwidth communication to subscriber 12, while still providing lower bandwidth communication to central office 14. ADSL communication is well-adapted for applications, such as video-on-demand, multimedia, and Internet access, that transfer large volumes of information to subscriber 12 in response to shorter requests for information. In one specific embodiment, downlink data rate 32 is approximately 1.5 Mbps, whereas uplink data rate 34 is approximately 750 kbps. In other embodiments, downlink data rate 32 may be six Mbps or more depending on the specific XDSL technology employed, the quality and length of subscriber line 16, and the contribution of noise and distortion from other components in communication system 10.

XDSL technology provides data service using existing subscriber lines 16 without interrupting normal telephone service. This is accomplished by a separation technique,

such as frequency division multiplexing (FDM), to separate frequencies that provide telephone service from those frequencies that provide data service. Dynamic noise cancellation techniques and a guard band between the data and phone service frequencies ensure reliable and simultaneous access to data and phone service over subscriber line 16. For example, subscriber 12 may simultaneously engage in both a data communication session using computer 22 and a voice conversation using telephone 20.

10 In operation, communication system 10 provides phone and data service to subscriber 12. Subscriber 12 accesses phone service by using telephone 20 to initiate a call. Upon going off-hook, communication system 10 establishes a circuit between telephone 20 and telephone switch 56 using interface 24, phone line 26, splitter 25, subscriber line 16, splitter 50, and one of phone lines 52. Upon establishing this telephone circuit, subscriber 12 using telephone 20 receives POTS service from telephone switch 56.

20 To access data service, subscriber 12 turns on computer 22, executes a program, such as an Internet browser, or performs some other affirmative or passive activity that generates a request, command, data packet, electrical tone, or other suitable information or signal that indicates a need for data service. In one embodiment, modem 30 repetitively 25 transmits the need for data service in a request interval, where the request interval comprises the time length of the request and the silent interval until the next request. Alternatively, the need for data service indicated at subscriber 12 may be based on the establishment of a closed 30 circuit between subscriber 12 and central office 14 or on one or more analog or digital signal transitions. Modem 30 communicates the need to communication server 58 at central office 14 using interface 24, data line 28, splitter 25, subscriber line 16, splitter 50, and one of data lines 54.

35 As described in detail below, communication server 58 detects the need for data service and selects an XDSL modem at communication server 58 to communicate with XDSL modem 30 in computer 22. Upon establishing a 40 modem connection between modem 30 in computer 22 and a selected modem in communication server 58, subscriber 12 engages in a data communication session with communication network 64 using network device 60. In addition, computer 22 may function as a gateway into communication 45 network 10 for other devices coupled to network interface 31 using link 18.

XDSL technology allows simultaneous use of subscriber line 16 for both phone and data service using the existing twisted pair wiring in communication system 10. In one 50 embodiment, splitter 50, communication server 58, and network device 60 are located at central office 14 to provide an efficient and modular provisioning of XDSL data service to subscribers 12. However, splitter 50, communication server 58, and network device 60 may be located outside 55 central office 14 without departing from the scope of the present invention.

FIG. 2 illustrates in more detail communication server 58. Data lines 54 associated with subscriber lines 16 are coupled to a switch 70. In one embodiment, each data line 54 60 corresponds to an associated subscriber line 16 and its related subscriber 12. Switch 70 couples selected data lines 54 to output lines 72 that in turn couple to modem pool 74. The format of signals on data lines 54 and output lines 72 is the same as the format of signals on subscriber lines 16. For 65 example, if communication system 10 adopts XDSL technology, signals on data lines 54 and output lines 72 are modulated using XDSL techniques.

Modems in modem pool 74 convert signals in an appropriate XDSL communication protocol into digital data in an appropriate digital protocol on digital lines 76. A multiplexer 78 is coupled to digital lines 76 and combines the signals on digital lines 76 into a fewer number of multiplexed digital lines 62. In one embodiment, multiplexer 78 combines information for delivery to network device 60 using a single multiplexed digital line 62.

A controller 80 is coupled to data lines 54 using a link 82. Controller 80 is also coupled to switch 70 and modem pool 74 using links 84 and 86, respectively. Controller 80 detects a need for data service generated by subscribers 12 and communicated over subscriber lines 16 to data lines 54. In response, controller 80 using link 84 directs switch 70 to couple a selected subset of data lines 54 to selected output lines 72 that couple to modems in modem pool 74. For example, controller 80 may monitor one thousand data lines 54 to provide XDSL data services using one hundred modems in modem pool 74.

Controller 80 also receives information from modem pool 74 using link 86 to determine status information of modems in modem pool 74. As digital lines 76 become inactive for a predetermined period of time, modem pool 74 detects this inactivity and generates a timeout indication for communication to controller 80. Upon receiving the timeout indication, controller 80 releases the inactive modem in modem pool 74 for later use.

In operation, communication server 58 detects a need for data service on a selected data line 54. This need may be indicated by current voltages, electrical tones, data link frames, packets, or any other suitable analog or digital protocol or data sequencing. Controller 80 detects the need using link 82 and configures switch 70 to provide a coupling between the selected data line 54 and one of the output lines 72 coupled to a selected modem pool 74. The selected modem translates bidirectional communication between a communication protocol on output line 72 and a digital protocol on digital line 76. Multiplexer 78 translates information between digital lines 76 and one or more multiplexed digital lines 62.

FIG. 3 illustrates in more detail controller 80. Data lines 54 through link 82 are coupled to polling circuitry 100. In one embodiment, polling circuitry 100 includes a number of terminals 102 corresponding to each data line 54. A switch 104 having a conductive probe 106 contacts terminals 102 to sample the signal on the associated data line 54. Polling circuitry 100 may comprise electromagnetic components, such as a relay or switch, solid state circuitry, or both. It should be understood that the present invention embodies any polling circuitry 100 that allows successive or selective sampling of data lines 54.

Transceiver 108 receives a selected signal 110 from polling circuitry 100. A detector 112 is coupled to transceiver 108, which in turn is coupled to processor 116. Detector 112 may include a media access controller (MAC) and associated memory to detect and store frames or packets of an appropriate digital protocol. Detector 112 may also include less complicated circuitry to detect current voltages, electrical tones, data bit transmissions, or other analog or digital information generated by transceiver 108.

Transceiver 108 and detector 112 may collectively be represented as modem 115, as indicated by the dashed line. Modem 115 provides an interface between the XDSL communication protocol of communication system 10 and processor 116. Modem 115 also includes similar components and performs similar functions as modem 30 in computer 22.

to enable modem 30 and modem 115 to exchange information using XDSL technology. Throughout this discussion, the term detector may refer to detector 112 or collectively modem 115.

5 A processor 116 is coupled to detector 112 and controls the overall operation of controller 80. A timer 117 is coupled to processor 116. Processor 116 is coupled to input/output circuitry 118, which in turn is coupled to switch 70 and modem pool 74 using links 84 and 86, respectively. Processor 116 is also coupled to switch 104 of polling circuitry 100 using input/output circuitry 118. In one embodiment, processor 116 controls the data line selection, dwell time, and other suitable parameters of polling circuitry 100.

15 Processor 116 is also coupled to database 120 that includes a program 121, an activity table 122, a line profile table 124, and a subscriber table 126. Database 120 stores information as one or more tables, files, or other data structure in volatile or nonvolatile memory. All or a portion of database 120 may reside at controller 80, within communication server 58, within central office 14, or at another location in communication system 10. For example, several communication servers 58 in one or more central offices 14 can access database 120 stored in a central location to provide more intelligent management and provisioning of 20 XDSL data service in communication system 10. One or more central offices 14 may be coupled together and the resources of their associated communication servers 58 shared using simple network management protocol (SNMP) 25 techniques.

30 Program 121 contains instructions to be executed by processor 116 to perform the functions of controller 80. Program 121 may reside in database 120 as shown or may be integral to memory components in transceiver 108, detector 112, and/or processor 116. Program 121 may be written in machine code, pseudocode, or other appropriate programming language. Program 121 may include modifiable source code and other version control features that allow modification, debugging, and enhancement of the 35 functionality of program 121.

40 Activity table 122, described in more detail below with reference to FIG. 7, maintains status information on data lines 54, switch 70, and output lines 72. In particular, activity table 122 contains information on inactive and active data lines 54, data lines 54 corresponding to current 45 valid subscribers 16 of XDSL data service, and the mapping performed by switch 70 between data lines 54 and output lines 72. Moreover, activity table 122 includes information that specifies the inactivity of a modem in modem pool 74, the status of a data line 54 as dedicated, and any other 50 suitable information that enables processor 116 to monitor and control the operation of switch 70 and modem pool 74.

55 Profile table 124 stores profile information on data lines 54. This profile information reflects electrical or physical characteristics of data line 54, its associated subscriber line 16 and data line 28, intervening components such as interface 24, splitter 25, splitter 50, and polling circuitry 100, as well as any other component or factor that effects the 60 performance or electrical characteristics of signals received on data lines 54. Processor 116 may access profile table 124 and provide profile information to transceiver 108 using link 125. Alternatively, transceiver 108 may be a more robust and broadband device that does not need profile information from profile table 124. Processor 116 may also provide 65 profile information to program XDSL modems in modem pool 74 once a coupling is made to a selected data line 54. The existence and complexity of profile information in

profile table 124 depends on the requirements of transceiver 108 and XDSL modems in modem pool 74, as well as the complexity of signals that indicate a need for data service from subscriber 12.

Subscriber table 126 stores subscriber information indexed by one or more identifiers of subscriber 12, computer 22, modem 30, subscriber line 16, or other information that associates data line 54 with a particular subscriber 12. Subscriber table 126 includes subscriber connect times, session duration, session activity, session logs, billing data, subscriber account information, and any other suitable subscriber information. This information may be summarized and additional information included to generate billing and demographic data on subscribers 12 in communication system 10.

For example, subscriber table 126 may maintain summary statistics on the number of subscribers 12 served by communication server 58, the average connect time, load factors, time-of-day connection profiles, and other statistics to assess the communication facilities to be deployed at communication server 58, the over-subscription ratio that can be supported by communication system 10, and other provisioning and management issues. Furthermore, subscriber table 126 may combine subscriber information from one or more communication servers 58 in one or more central offices 14 in communication system 10.

Management interface 128 is coupled to processor 116 and database 120 and allows external access to the functionality of processor 116. Management interface 128 is also coupled to database 120, which allows modification of program 121, as well as remote access and modification of information in activity table 122, profile table 124, and subscriber table 126. In one embodiment, the telephone service provider or other entity that operates central office 14 or communication system 10 accesses management interface 128 to provide management and control over the operations of controller 80 and communication server 58. For example, the telephone service provider uses management interface 128 to access activity table 122 and/or subscriber table 126 to update the valid subscribers 12 that have access to communication server 58. A local or remote computer 130 is coupled to program interface 128 using an appropriate data link 132, such as a serial RS-232 link, to provide this management feature.

In operation, modem 30 in computer 22 indicates a need for data service, and communicates this need to an associated data line 54 using interface 24, data line 28, splitter 25, subscriber line 16, and splitter 50. In one embodiment, modem 30 transmits successive requests at a predetermined request interval. Processor 116 accesses activity table 122 to determine which data lines 54 to poll, depending on the active or inactive status of the data line 54, whether subscriber 12 corresponding to data line 54 is a current and valid subscriber, and other appropriate considerations. For example, activity table 122 may indicate valid and non-dedicated subscribers 12 to poll.

Polling circuitry 100 successively polls selected data lines 54, as directed by processor 116, using link 82 to detect a need for data service. For each data line 54 polled, processor 116 may access profile table 124 in database 120 and provide associated profile information to transceiver 108 using link 125. Polling circuitry 100 dwells on each data line 54 for a predetermined polling interval to detect a need. In one embodiment, the polling interval is at least two times a request interval of modem 30.

Upon detecting the need for data service associated with a selected data line 54 from polling circuitry 100, transceiver

108 may translate the information from the selected XDSL communication protocol employed on subscriber line 16 into digital or analog data for detection by detector 112. A media access controller (MAC) in detector 112 may transform serial digital data from transceiver 108 into a parallel digital format. Detector 112 receives the information translated by transceiver 108, and stores this information in a suitable memory location for access by processor 116. Processor 116 periodically accesses detector 112 to determine if a need for data service has been detected.

Upon detecting a need for data service, processor 116 accesses database 120 to determine the availability and status of modems in modem pool 74. Processor 116 selects an available modem from modem pool 74. Processor 116 then directs switch 70 to make the appropriate coupling between selected data line 54 and output line 72 coupled to the selected modem. Upon establishing coupling between modem 30 in computer 22 at subscriber 12 and a selected modem in modem pool 74, controller 80 continues to monitor the remaining data lines 54 using polling circuitry 100.

Processor 116 can transmit status or connection information to modem 30 in computer 22 using transceiver 108. This may be performed before, during, or after coupling the selected modem in modem pool 74 to data line 54. For example, processor 116 may send acknowledgment information to modem 30 that includes an indication that a modem is or is not available, an identification of the available modem, a time interval before modem 30 should attempt communication with the selected modem in modem pool 74, or any other suitable information. Furthermore, processor 116 may access information from subscriber table 126, such as billing and account information, historical connection information, or other suitable subscriber information, and transmit this information separate to or as part of the acknowledgment information described above.

Processor 116 may also transmit connection information and updated billing and subscriber information to modem 30 at computer 22 using link 86 and the associated XDSL modem in modem pool 74. This information may include the length of the current session, the current balance in the account of subscriber 12, as well as any other suitable information that relates to the account or activity of subscriber 12 with communication server 58. Generally, processor 116 may communicate any suitable information stored at or made available to controller 80 to subscribers 12 using transceiver 108 or the associated modem in modem pool 74.

FIG. 4 illustrates in more detail switch 70 and modem pool 74 of communication server 58. Data lines 54 are coupled to switch 70, now shown in more detail as a cross-bar or cross-point matrix switch. In this particular embodiment, data lines 54 correspond to lines 150, and output lines 72 correspond to lines 152 in switch 70. The number of lines 150 (n) is greater than the number of lines 152 (m). This allows switch 70 to couple selected data lines 54 to a reduced number of output lines 72 to provide an over-subscription of XDSL data service in communication system 10. For example, switch 70 couples the second of lines 150 to the last of lines 152 by establishing connection 154. Similarly, switch 70 couples the last of lines 150 and the first of lines 152 by establishing connection 156.

Although switch 70 is shown in FIG. 4 to be a cross-bar or cross-point matrix switch, it should be understood that any device that can couple a number of data lines 54 to a reduced number of output lines 72 may be used. Switch 70

may incorporate electromagnetic components, such as relays and contacts, or may be implemented in whole or in part using one or more solid state devices.

Modem pool 74 includes XDSL modems 160 associated with output lines 72 from switch 70. Modems 160 translate information between an appropriate XDSL communication protocol on output lines 72 and an appropriate digital protocol on digital lines 76. In one embodiment, modems 160 may be similar in construction and operation to modem 30 at subscriber 12. A detector 162 coupled to modems 160 detects the activity of modems 160 to determine if the line has become inactive for a predetermined interval of time. For example, if one of the modems 160 does not display activity over a five-minute interval, detector 162 generates a timeout indication to notify processor 116 of the inactive modem. Processor 116 releases or decouples the inactive modem for later subscriber sessions. In one embodiment, detectors 162 may include one-shot timers or other retriggerable timers set for a predetermined time interval to detect the inactive status of modems 160.

Detector 162 is a monitoring circuit that passes through the digital output of modems 160 to digital lines 76 for presentation to multiplexer 78. Multiplexer 78 may combine signals from digital lines 76 into a single multiplexed digital line 62. Alternatively, multiplexer 78 may employ any suitable reduction ratio that places signals on digital lines 76 on a fewer number of multiplexed digital lines 62.

Processor 116 may directly communicate with modems 160 using link 164. For example, link 164 allows processor 116 to program modems 160 with profile information retrieved from profile table 124. Link 164 also supports communication between processor 116 and selected subscribers 12 during an active subscriber session using modems 160. Moreover, link 164 allows processor 116 to monitor the information received from and transmitted to subscribers 12 during a communication session.

In operation, switch 70 couples a selected subset of data lines 54 to output lines 72 in response to signals received from controller 80 using link 84. Each of the output lines 72 is coupled to an associated modem 160 which translates the information formatted in an analog communication protocol, such as XDSL, into an appropriate digital signal. The digital information output from modems 160 passes through detector 162, which monitors the activity on the output line of modems 160. If detector 162 senses inactivity over a predetermined interval, a timeout indication is provided to processor 116 using link 86. Signals on digital lines 76 may be reduced to fewer multiplexed digital lines 62 using multiplexer 78.

FIG. 5 illustrates in more detail transceiver 108 in controller 80. To receive information, transceiver 108 includes filters and magnetics 170 to condition the signal from selected data line 54. The conditioned signal is provided over differential lines 172 to analog bit pump 174. Bit pump 174 performs the specific demodulation technique for the chosen XDSL communication protocol. For example, bit pump 174 may execute a discrete multi-tone demodulation (DMT) or carrierless amplitude phase demodulation (CAP) to demodulate an XDSL signal on differential lines 172 into a digital stream on line 176. Logic and timing circuitry 178 contains decode logic, timing and synchronization circuitry, steering logic, and other appropriate digital processing circuitry to produce a data signal on receive data line 180 and a corresponding clock signal on clock line 182 for delivery to detector 112 or processor 116. Detector 112 may include a MAC to support any digital protocol or signal detection

that indicates a need for XDSL data service. The data may be in non-return-to-zero format or any other suitable format.

To transmit information, transceiver 108 receives a data signal on transmit data line 184 from detector 112 or processor 116. Using the clock line 182, logic and timing circuitry 178 digitally processes signals received on transmit data line 184 for delivery to analog bit pump 174. Using an appropriate modulation technique, such as DMT or CAP, analog bit pump 174 produces an analog signal for delivery over differential lines 172 to filters and magnetics 170 for transmission over selected data line 54.

FIG. 6 illustrates in more detail a specific embodiment of detector 112 that includes a MAC 113 and a memory 114. MAC 113 is coupled to receive data line 180 and clock line 182, and translates received data from a serial data format, such as a non-return-to-zero format, into an appropriate parallel digital format. MAC 113 translates the data from the chosen digital protocol and provides the data to memory 114 using data bus 190. MAC 113 also provides an address to memory 114 using address bus 192 to specify the location in memory 114 to store data provided on data bus 190. In addition, MAC 113 provides a write signal to memory 114 using control line 194.

To transmit data, MAC 113 provides a read signal to memory 114 using control line 194, and an associated address of the data to be read using address bus 192. In response, memory 114 provides the requested data on data bus 190. MAC 113 translates the data into the selected digital protocol for placement on transmit data line 184.

FIG. 7 illustrates one embodiment of activity table 122 stored in database 120 of controller 80. Processor 116 accesses and modifies entries in activity table 122 to direct the operation of controller 80. In addition, management interface 128 provides external access to activity table 122. For example, a telephone service provider using management interface 128 can add, delete, or otherwise modify entries in activity table 122 to maintain a listing of valid subscribers 12. Database 120 stores some or all of the status information shown in this exemplary activity table 122, as well as other information that may be used by processor 116 to direct the activities of controller 80.

Activity table 122 includes a data line column 200 that contains an address or other appropriate identifier of data lines 54 associated with subscriber lines 16 and their related subscribers 12. Status column 202 indicates the status of data line 54 identified in data line column 200. For example, status column 202 may contain one or more indications that the associated data line 54 is inactive (I), active (A), or dedicated (D). A timeout column 204 indicates whether detector 162 in modem pool 74 has detected a timeout associated with a particular data line 54. A modem column 206 includes an identifier of the modem 160 associated with the corresponding data line 54.

An entry in activity table 122 corresponds to a row that designates a selected data line 54 in data line column 200, the status of the selected data line 54 in status column 202, a timeout indication of the selected data line 54 in timeout column 204, and the modem associated with the selected data line 54 in modem column 206. For example, entry 208 relates to data line "D1" which is inactive. Entry 210 represents data line "D2" which is inactive but dedicated to modem "M1." Entry 212 indicates that data line "D4" is active, coupled to modem "M3," but a timeout indication has been detected.

Subscribers 12 indicated in status column 202 as dedicated may be serviced by communication server 58 in a

specific way. Switch 70 in communication server 58 maintains a coupling between data line 54 corresponding to dedicated subscriber 12 and its associated and dedicated modem 160. In this manner, controller 80 need not detect a need for data service or reconfigure the couplings for data line 54 corresponding to dedicated subscriber 12. In this manner, communication server 58 provides the option of a different class of service for a dedicated subscriber 12 that desires uninterrupted access to XDSL communication facilities.

FIG. 8 is a flow chart of a method performed at controller 80 to couple data lines 54 to modems 160 in modem pool 74. The method begins at step 300 where processor 116 of controller 80 loads activity table 122 from database 120 which contains an entry for each valid subscriber 12 served by communication server 58. Using management interface 128, a telephone service provider may ensure that activity table 122 reflects valid subscribers 12 by monitoring past due accounts, the overuse of data service, successive invalid attempts to access communication server 54, or other factors that may cause subscribers 12 to be invalid. Processor 116 selects the first inactive and non-dedicated data line 54 indicated by the designation 'T' in status column 202 of activity table 122. Since switch 70 is configured to continuously couple dedicated subscribers 12 to their dedicated modems 160, processor 116 need not select an inactive data line 54 that is also dedicated, as indicated by the designation 'I/D' in status column 202.

Using input/output circuitry 118, processor 116 directs switch 104 of polling circuitry 100 to couple transceiver 108 to the selected inactive and non-dedicated data line 54 at step 304. If appropriate, processor 116 accesses profile table 124 in database 120 and provides profile information for the selected data line 54 to transceiver 108 using link 125 at step 306. Processor 116 initializes timer 117 with a predetermined polling interval at step 308.

If a need for data service has not been detected by transceiver 108 at step 312, then processor 116 checks timer 117 at step 314. If the polling interval monitored by timer 117 has not expired at step 314, then processor 116 again determines if a need has been detected at step 312. However, if the polling interval monitored by timer 117 has expired at step 314, processor 116 selects the next inactive and non-dedicated data line 54 as indicated in status column 202 of activity table 122 at step 316, and returns to step 304.

If a need for data service is detected at step 312, the associated information may be further processed by detector 112 and placed in memory for access by processor 116 at step 318. Before, during, or after step 318, transceiver 108, detector 112, and/or processor 116 may validate the need for data service. Validation may be performed at a low level, such as a verification of the checksum or detection of an incomplete transmission, or at a higher level, such as a verification of an identifier, password, or other security information that provides access to communication server 58. Validation contemplates any level of validation or security handshake that confirms that the received need is valid and accepted by controller 80.

Upon selecting an unused modem at step 332, processor 116 generates a command that directs switch 70 to couple the selected data line 54 to the selected modem 160 at step 333. Processor 116 may communicate status or connection information to subscriber 12 using transceiver 108 or the selected modem 160 at step 334. Processor 116 updates activity table 122 at step 336 to indicate that the selected data line 54 is now active and that the selected modem 160

is now being used. Processor 116 directs activity detector 162 to initialize the inactivity interval for the selected modem 160 at step 338. Processor 116 then selects the next inactive and non-dedicated data line 54 in activity table 122 at step 316, and returns to step 304.

FIG. 9 is a flow chart of a method for monitoring and decoupling modems 160 due to inactivity. It should be understood that the methods described with reference to FIGS. 8 and 9 may be performed simultaneously or in alternative succession by processor 116 to couple and decouple data lines 54 with modems 160. The method begins at step 400 where processor 116 loads activity table 122 which contains an entry for each valid subscriber 12 served by communication server 58. Processor 116 selects a first active and non-dedicated data line 54 as indicated by the designation "A" in status column 202 of activity table 122 at step 402. Since switch 70 is configured to maintain a coupling between dedicated subscribers 12 and their dedicated modems 160, processor 116 need not select an active data line 54 that is also dedicated, as indicated by the designation "A/D" in status column 202.

Processor 116 retrieves timeout status for modem 160 associated with the selected active data line 54 from detector 162 using link 86 and input/output circuitry 118 at step 404. Processor 116 determines if a timeout has occurred for the selected active data line 54 at step 408. If a timeout has not occurred, processor 116 selects the next active and non-dedicated data line 54 as indicated in status column 202 of activity table 122 at step 410, and returns to step 404.

If a timeout has occurred at step 408, processor 116 may communicate status or connection information to subscriber 12 associated with the selected active data line 54 using transceiver 108 or the associated modem 160 at step 412. Processor 116 generates a command to direct switch 70 to decouple the active data line 54 from its associated modem 160 at step 414. Processor 116 updates activity table 122 at step 416 to indicate that data line 54 is now inactive and that the associated modem 160 is available for another subscriber session.

Although the present invention has been described with several embodiments, a myriad of changes, variations, alterations, transformations, and modifications may be suggested to one skilled in the art, and it is intended that the present invention encompass such changes, variations, alterations, transformations, and modifications as fall within the spirit and scope of the appended claims.

What is claimed is:

1. A communication system, comprising:
a plurality of computers located at a plurality of subscriber premises, each computer having a first XDSL modem to communicate information;
a plurality of twisted pair subscriber lines coupled to the plurality of computers, each twisted pair subscriber line forming a local loop;
a splitter remotely located from the plurality of subscriber premises and coupled to the local loops formed by the twisted pair subscriber lines, the splitter to split each twisted pair subscriber line into a twisted pair data line and a twisted pair phone line; and
a communication server coupled to the twisted pair data lines of the splitter, the communication server having a plurality of second XDSL modems to communicate information with the first XDSL modems using the twisted pair subscriber lines and associated twisted pair data lines, the communication server to couple the second XDSL modems to selected subsets of the

twisted pair data lines, wherein the first XDSL modems at the subscriber premises and the second XDSL modems at the communication server provide high bandwidth data service using the twisted pair subscriber lines.

2. The communication system of claim 1, further comprising a telephone switch coupled to the twisted pair phone lines of the splitter, the telephone switch operable to provide telephone service to the subscriber premises using the twisted pair subscriber lines and associated twisted pair phone lines.

3. The communication system of claim 2, further comprising a plurality of telephone located at the subscriber premises and coupled to the twisted pair subscriber lines, each telephone operable to receive telephone service provided by the telephone switch.

4. The communication system of claim 1, further comprising a plurality of second splitters located at the subscriber premises, each second splitter operable to split each twisted pair subscriber line into a twisted pair data line and a twisted pair phone line, the twisted pair data line being coupled to the first XDSL modem.

5. The communication system of claim 1, wherein:
the first XDSL modems are operable to communicate information to the second XDSL modems at a first rate; and
the second XDSL modems are operable to communicate information to the first XDSL modems at a second rate greater than the first rate.

6. The communication system of claim 1, wherein the communication server further comprises:

a switch coupled to the twisted pair data lines, the switch operable to couple a selected subset of the twisted pair data lines to the second XDSL modems; and
a controller coupled to the switch and the twisted pair data lines, the controller operable to detect a need for data service from at least one computer over an associated twisted pair data line, the controller further operable to direct the switch to couple the associated twisted pair data line to a selected second XDSL modem in response to detecting the need.

7. The communication system of claim 1, wherein the communication server further comprises:

a switch coupled to the twisted pair data lines, the switch operable to couple a selected subset of the twisted pair data lines to the second XDSL modems; and
a controller coupled to the switch and the twisted pair data lines, the controller operable to poll in succession the twisted pair data lines to detect a need for data service from at least one computer over an associated twisted pair data line, the controller further operable to direct the switch to couple the associated twisted pair data line to a selected second XDSL modem in response to detecting the need.

8. The communication system of claim 1, wherein the number of second XDSL modems is less than the number of twisted pair subscriber lines.

9. The communication system of claim 1, wherein the splitter and the communication server are located at a central office.

10. A communication server coupled to a plurality of twisted pair data lines, each twisted pair data line coupled to an associated twisted pair subscriber line forming a local loop to a subscriber, the communication server comprising:
a plurality of XDSL modems;

a switch coupled to the plurality of XDSL modems, the switch to couple selected subsets of the twisted pair data lines to the XDSL modems;

a detector coupled to the switch and to detect a need for data service on a selected twisted pair data line; and a processor coupled to the detector, the processor to select one of the plurality of XDSL modems in response to detecting the need, the processor further to direct the switch to couple the selected twisted pair data line to the selected XDSL modem, wherein the selected XDSL modem provides high bandwidth data service to the subscriber using the twisted pair subscriber line.

11. The communication server of claim 10, wherein the XDSL modems perform data modulation using asymmetric digital subscriber line technology.

12. The communication server of claim 10, wherein the XDSL modems are operable to receive information at a first rate and to transmit information at a second rate greater than the first rate.

13. The communication server of claim 10, wherein the switch comprises a cross-point matrix switch.

14. The communication server of claim 10, further comprising polling circuitry having a plurality of inputs coupled to the twisted pair data lines and a single output coupled to the detector, the polling circuitry to couple in succession the inputs to the output.

15. The communication server of claim 10, further comprising an activity table coupled to the processor, the activity table specifying a plurality of inactive twisted pair data lines, the processor operable to access the activity table and to direct the polling circuitry to poll the inactive twisted pair data lines specified in the activity table.

16. The communication server of claim 10, further comprising an activity table coupled to the processor, the activity table specifying a plurality of active twisted pair data lines, the processor operable to update the activity table to specify the selected twisted pair data line as one of the active twisted pair data lines.

17. The communication server of claim 10, further comprising an activity detector coupled to the XDSL modems, the activity detector operable to detect a predetermined period of inactivity of the XDSL modems.

18. The communication server of claim 10, further comprising a multiplexer coupled to the XDSL modems, the multiplexer operable to combine information received from the XDSL modems into a single multiplexed signal.

19. The communication server of claim 10, wherein the number of XDSL modems is less than the number of twisted pair subscriber lines.

20. The communication server of claim 10, wherein the communication server is located at a central office.

21. A method for coupling selected subsets of a plurality of twisted pair subscriber lines to a plurality of XDSL modems in order to off-load high bandwidth data service from a telephone switch, the method comprising:

splitting each twisted pair subscriber line into a twisted pair data line and a twisted pair phone line, each twisted pair subscriber line forming a local loop to a subscriber; detecting a need for data service on a selected inactive twisted pair data line;

selecting one of the plurality of XDSL modems in response to detecting the need; and

coupling the selected inactive twisted pair data line to the selected XDSL modem, wherein the high bandwidth data service is provided to the subscriber using the selected XDSL modem rather than the telephone switch.

22. The method of claim 21, further comprising the step of coupling the twisted pair phone lines to the telephone switch to provide telephone service.

23. The method of claim 21, wherein the XDSL modems are located at a central office.

24. The method of claim 21, further comprising: reading an activity table to identify an inactive twisted pair data line; and coupling the detector to the identified inactive twisted pair data line.

25. The method of claim 21, further comprising: reading an activity table to identify an inactive twisted pair data line; coupling the detector to the identified inactive twisted pair data line; and maintaining the coupling between the detector and the identified inactive twisted pair data line for a predetermined interval.

26. The method of claim 21, further comprising: reading an activity table to identify an inactive twisted pair data line; and providing a receiver with a profile of the identified inactive twisted pair data line.

27. The method of claim 21, further comprising: reading an activity table to identify an inactive and non-dedicated twisted pair data line; and coupling the detector to the identified inactive and non-dedicated twisted pair data line.

28. The method of claim 21, further comprising: reading an activity table to identify an inactive twisted pair data line associated with a valid and non-dedicated subscriber; and

coupling the detector to the identified inactive twisted pair data line.

29. The method of claim 21, further comprising the step of updating an activity table to indicate that the selected inactive twisted pair data line is active.

30. The method of claim 21, wherein the selected inactive twisted pair data line is redesignated an active twisted pair data line, further comprising the following steps to decouple the active twisted pair data line:

10 detecting a predetermined period of inactivity of the selected XDSL modem; and decoupling the active twisted pair data line and the selected XDSL modem in response to detecting the predetermined period of inactivity.

15 31. The method of claim 21, wherein the selected inactive twisted pair data line is redesignated an active twisted pair data line, further comprising the following steps to decouple the active twisted pair data line:

detecting a predetermined period of inactivity of the selected XDSL modem; decoupling the active twisted pair data line and the selected XDSL modem in response to detecting the predetermined period of inactivity; and

25 32. The method of claim 21, wherein the number of XDSL modems is less than the number of twisted pair subscriber lines.
